

Project

Initialize Project & Install Dependencies

Open your terminal, create a new directory for your project, initialize it, and install the native MongoDB driver, Express, and Dotenv (to manage your connection strings safely).

Create the Database Connection Module

Using the native mongodb package requires managing the client connection manually. Create function to reuse that same database instance across your app.

Create the Main App File (server.js)

Combine everything in your entry point. This file sets up Express middleware, points to the routing rules, calls the database initializer, and sets the app to listen on your configured port.

Share the app.js or the main file in your project, Package.json and project related files and folder. Do not send node_module or package-lock.json
